

Figure 1: Decision tree of how those with HCM will be targeted for SCD management

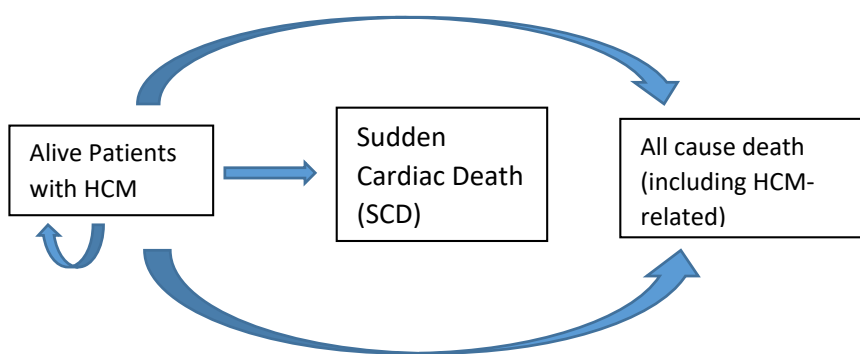

Figure 2: Decision tree of possible health states and transitions in the economic model

The HCM-SCD survival patient-level risk model is used for each **annual** cycle to determine whether a patient: (1) remains in their current health state, (2) has SCD event, (3) dies from other, HCM or non-HCM related causes.

The probability of SCD event each year after baseline was calculated using the HCM-SCD model for which we will be able to use individual level data.

The probability of dying from causes other than SCD is calculated...
